AI strep throat diagnosis from pharyngeal images: what the new study shows

27 November 2026 · 4 min read · blogs.iictp.org/ai-strep-throat-diagnosis-pharyngeal-images

Short answer: AI strep throat diagnosis here means a model that combines throat photographs with clinical details to separate Group A streptococcus pharyngitis from viral upper respiratory infection, published in npj Digital Medicine on 25 November 2026. The authors report an area under the curve of 0.917 in development and internal validation. It matters because better discrimination could reduce unnecessary antibiotics, but external and prospective testing has not yet been done.

TL;DR The short version

- A model in npj Digital Medicine on 25 November 2026 combines throat photographs with clinical details to tell strep throat from viral infection.
- The authors report an area under the curve of 0.917 in development and internal validation.
- External and prospective testing has not been done, so it is not ready for clinical use; this is not clinical advice.

What is this AI strep throat model?

Group A streptococcus (GAS) pharyngitis and viral infections can look alike on symptoms. Okiyama and colleagues built a multimodal model that reads images of the pharynx and structured clinical data together. The images came from a dedicated pharyngeal camera database.

How it works

An image network of the Swin Transformer type analyses the photographs. Its output is combined with clinical metadata by gradient-boosted decision trees, a method that builds many small decision rules in sequence. The model was compared with image-only and metadata-only versions and with approximations of the Centor and McIsaac clinical scores.

What is new compared with clinical scores

Centor and McIsaac scores add up a few signs and history items. The study tests whether information in the appearance of the throat adds to that, and whether fusing both sources beats either alone.

Results reported by the authors

- Data: 6,666 visits and 119,988 images from 44 facilities, collected from March 2023 to August 2025.
- GAS against non-GAS cases (influenza A or B and COVID-19): AUC 0.917 for the fusion model, 95% confidence interval 0.907 to 0.926.
- Image only: 0.902. Metadata only: 0.871. The fusion model also beat proxy Centor and McIsaac scores.
- At a pre-set threshold with specificity of at least 0.90, sensitivity was 0.761.
- Simulations suggested 23% to 56% fewer antibiotic prescriptions across GAS prevalence of 5% to 20%.
- The article is peer reviewed and open access.

Limitations and open questions

- Validation was internal. The authors say external validation and prospective evaluation are needed.
- The comparison group was influenza and COVID-19, not every viral or bacterial cause of sore throat.
- Prescription reductions come from simulation, not from observed practice.
- At the reported threshold, roughly one in four GAS cases would be missed by the model alone.
- The study was funded by Aillis, which makes the camera used. Four authors are executives or employees who own shares, and the company took part in design, analysis and writing.

Sources were read on 27 November 2026. Products, rules and data change, so check the linked originals before you rely on any detail.

How to appraise it before any use

1. Check whether your patients resemble the study population and which camera is required.
2. Ask for external validation against laboratory testing in your setting.
3. Work out predictive values at your local prevalence, not only the AUC.
4. Decide what happens after a negative result, especially for higher-risk patients.
5. Confirm regulatory status in your country.
6. Audit antibiotic use and missed cases if you ever pilot it.

What it means for primary care doctors

Treat the result as promising evidence for a diagnostic aid, not as a replacement for testing or judgement. The most useful reading habit is to link the headline AUC to the operating threshold and the funder statement. Our summary of ambient AI note evaluation shows the same need to test tools in real workflows.

Frequently asked questions

- **Can AI diagnose strep throat from a photo?** This model uses photos plus clinical data and showed high discrimination in internal validation only.
- **How accurate was it?** AUC 0.917, with sensitivity 0.761 at specificity of at least 0.90.
- **Will it cut antibiotic use?** Simulations suggested reductions, which are not yet observed in practice.
- **Who funded it?** Aillis, the maker of the camera used.
